

Lab 08 exercise 01

One line is read at a time from the file by means of input redirection.

The input of the `read` command is read from the file specified as argument. The cycle executes its core until the `read` execution fails (i.e., the exit status of `read` is non-zero)

The line length can be calculated using the `wc -c` command or the bash builtin function `${#var}`.

While the first calculates the length in bytes of the string, the second one also uses the locale to elaborate characters not in the ASCII table to provide a more precise result.
